BACTERIAL GENETICS, CONTINUED

MUTATION

Change in genetic material (base sequence of the DNA)

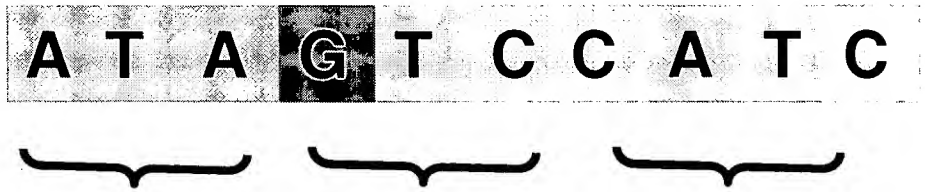
TYPES OF MUTATION

Base substitution

(May or may not be Missense)

Nonsense

Frameshift



HOW DOES MUTATION OCCUR??

Mistakes in replication - chemical mutagens - radiation

Compounds that cause mutation are called mutagens

Mutations that occur without seeming cause are 'spontaneous'

Cells have safeguards and repair mechanisms

MUTATIONS CAN BE BENEFICIAL!

Why is mutation such a significant process in biology???

It makes natural selection and evolution possible

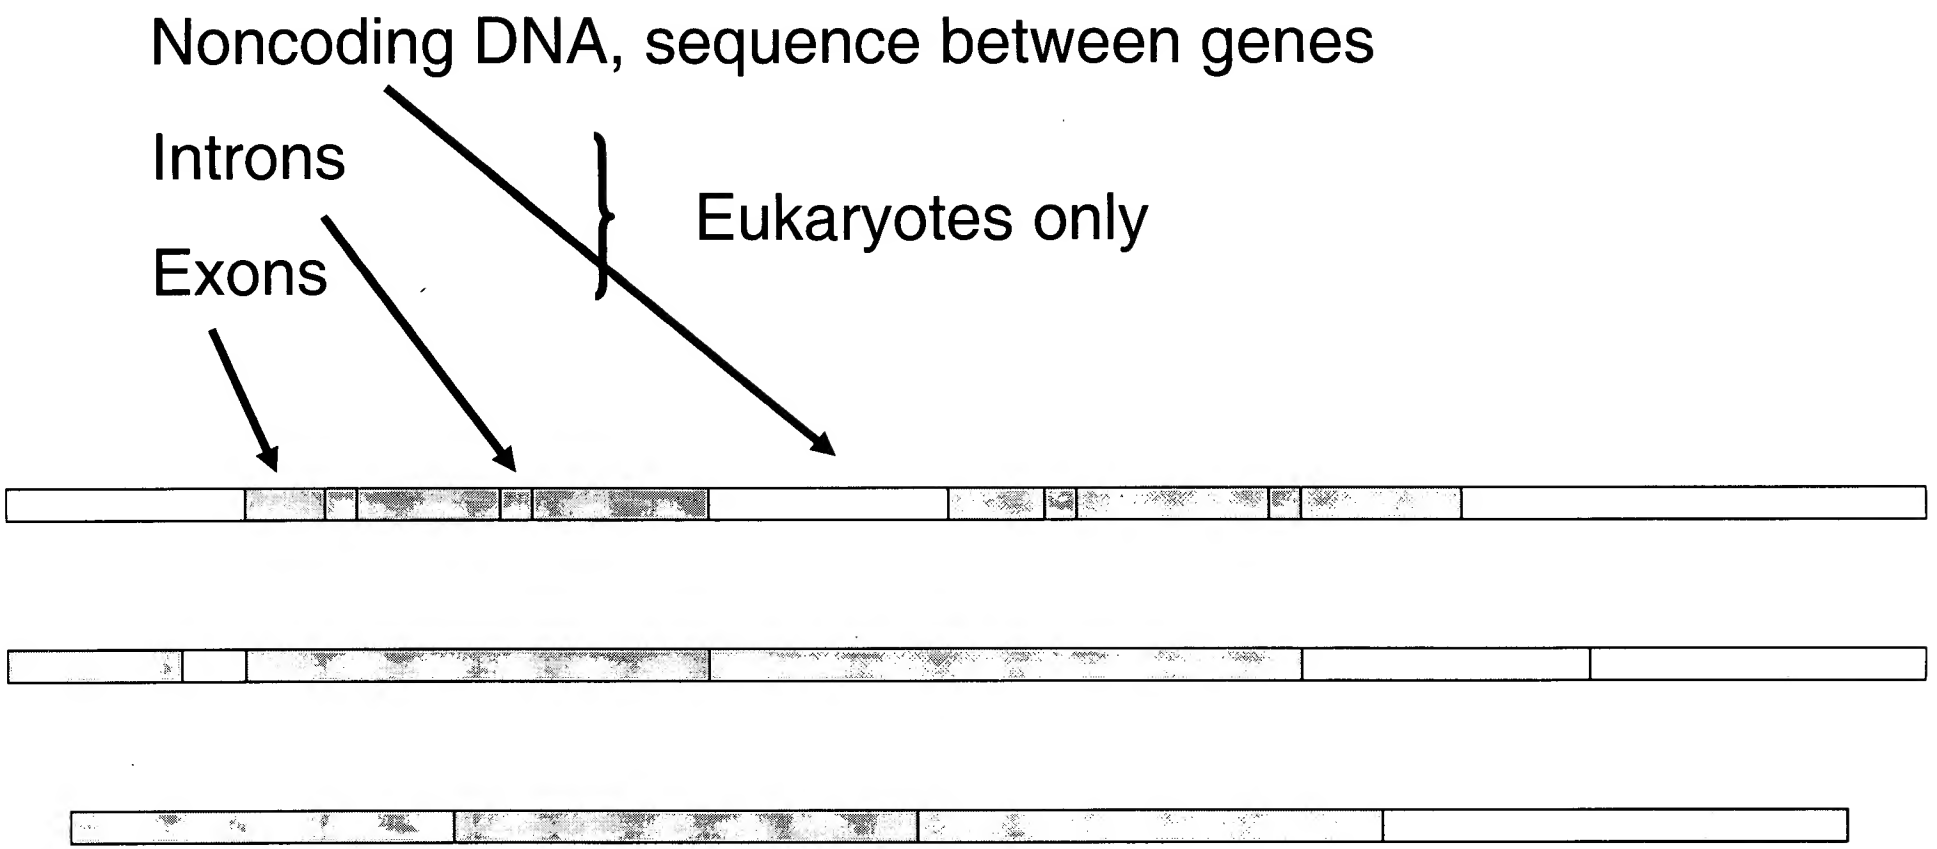
It's the foundation for all the variability we see around us (variability is key to our survival, and that of other species, including bacteria)

Mutations are the cause of genetic (inherited) disease

Mutation allows bacteria to respond to environmental change that we thrust upon them (e.g. antibiotic resistance)

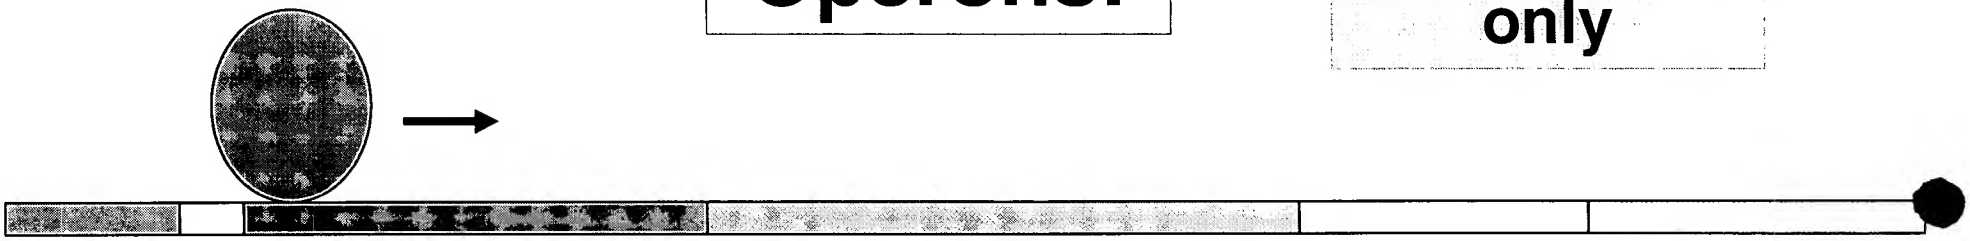
Deliberate and directed mutation is something we do in the laboratory to learn about genes and proteins. Mutant bacteria and mice have taught us VOLUMES about the human genome!

INTRONS, EXONS, NON-CODING DNA



Operons!

Prokaryotes only

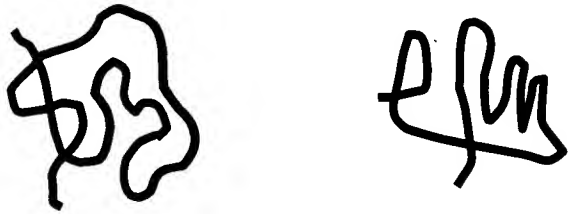


Gene 1

Gene 2

1 mRNA

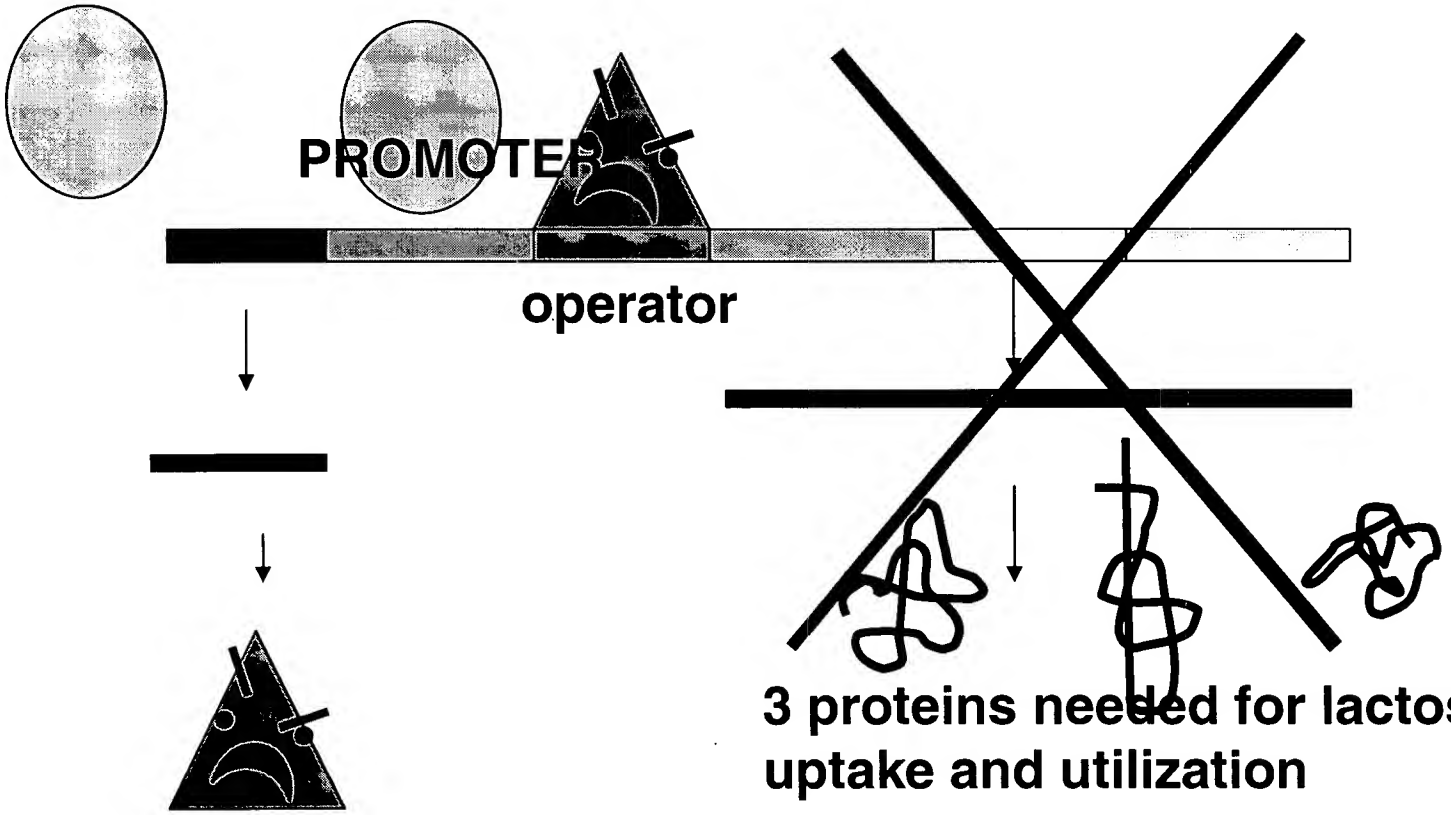
2,3 or more proteins!



PROTEIN 1

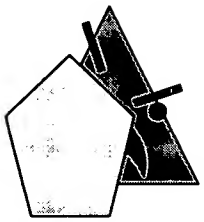
PROTEIN 2

The famous 'Lac' operon



3 proteins needed for lactose uptake and utilization

REPRESSOR PROTEIN



An inducer binds to repressor, rendering it non-functional

How are prokaryotes different from eukaryotes, genetically?

smaller genome

no nucleus

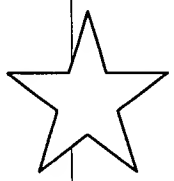
1 circular chromosome

no introns

less non-coding DNA

have operons

Let's review

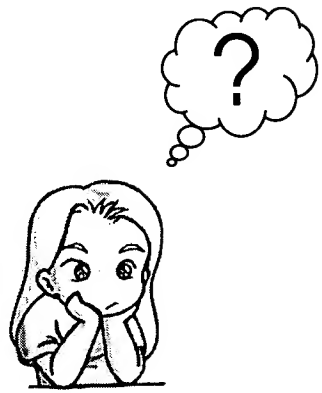


SHARE DNA by transduction, conjugation, and transformation

Prokaryotes reproduce by producing clonal copies of themselves.

Therefore, new combinations are not possible…..hmmm

Or are they?????



YES - NEW CHROMOSOMAL COMBINATIONS ARE POSSIBLE THROUGH MUTATION (occurs in eukaryotes also)

AND YES - NEW CHROMOSOMAL COMBINATIONS ARE POSSIBLE THROUGH 3 TYPES OF RECOMBINATION that do not occur in eukaryotes!

1. TRANSFORMATION

Transformation occurs when cells take up pieces of DNA from the environment

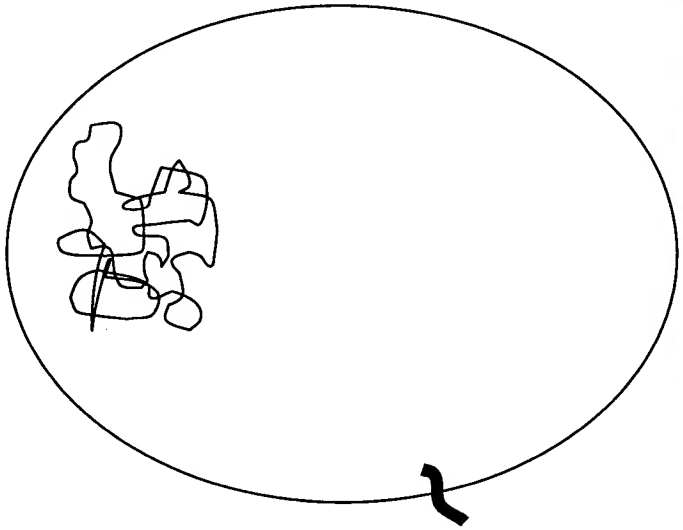
TRANSFORMATION

Pieces of DNA are taken into a bacterial cell from the environment

•The DNA usually comes from other cells that have broken apart

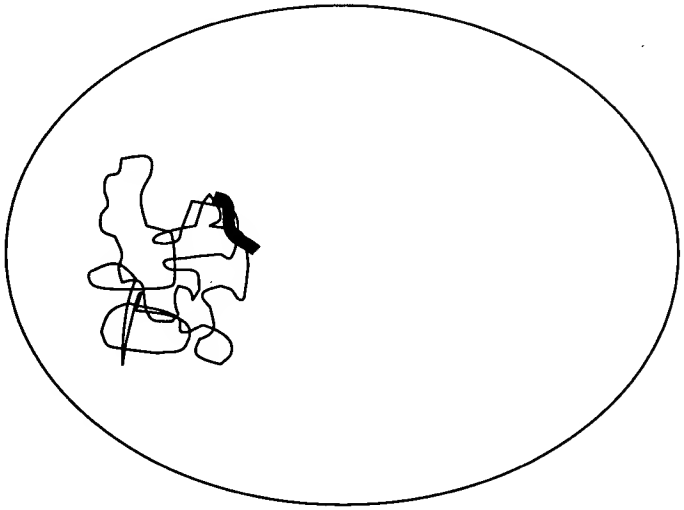
Cells only take up DNA under certain conditions

Frederick Griffith first discovered this process in 1928, using *Streptococcus pneumoniae*



DNA pieces in environment

Starting cell



New recombinant cell

Please read about Griffith's Experiment in your text

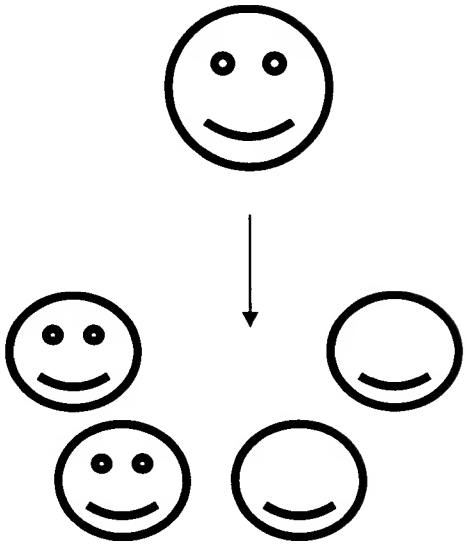
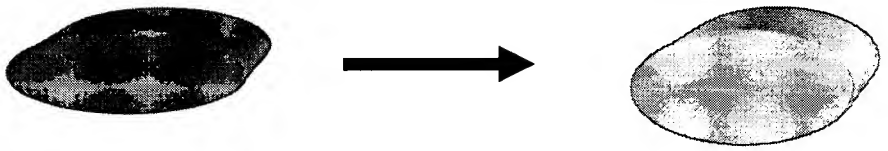
VERTICAL GENE TRANSFER



HORIZONTAL GENE TRANSFER



donor

recipient

2. TRANSDUCTION

Transduction occurs when bacteriophage infect cells, and carry bacterial DNA from cell to cell.

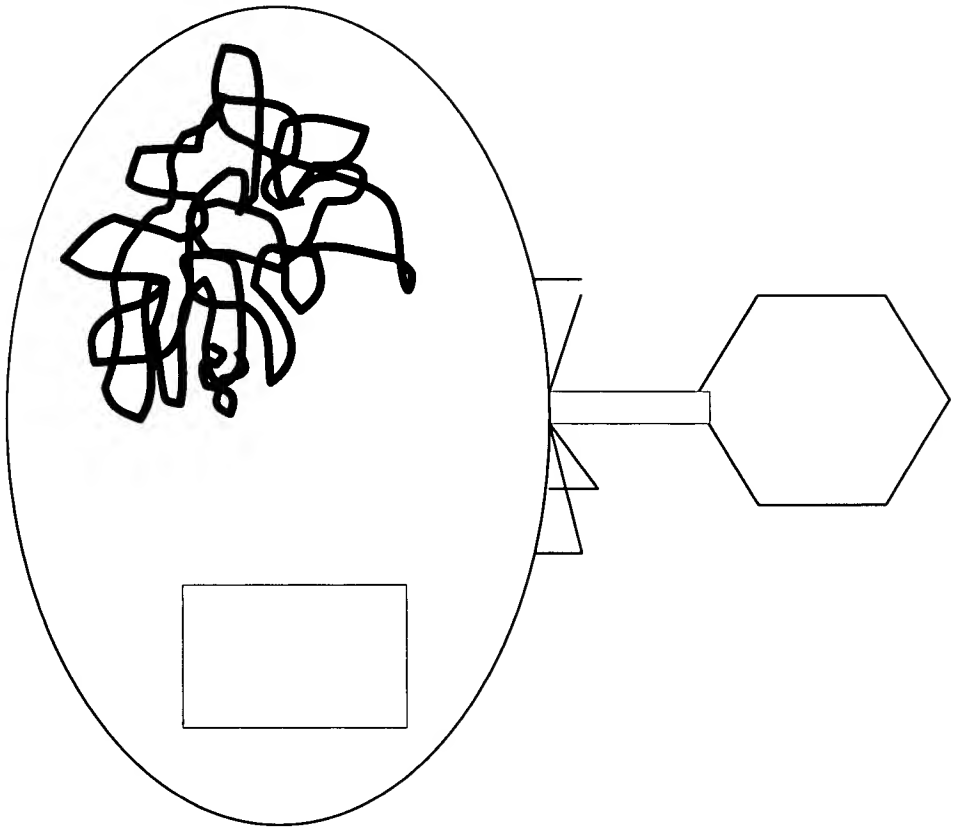
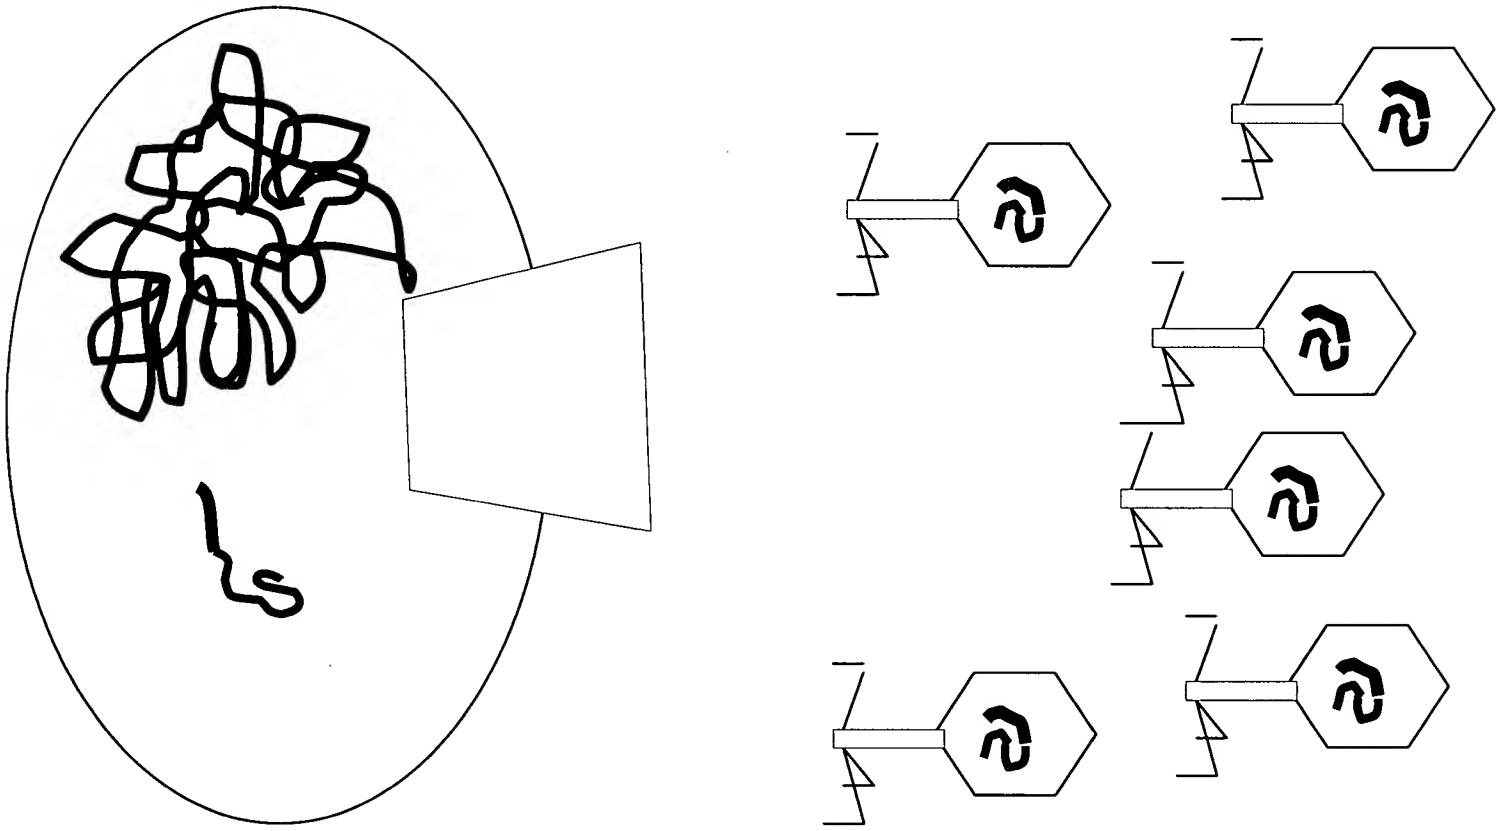
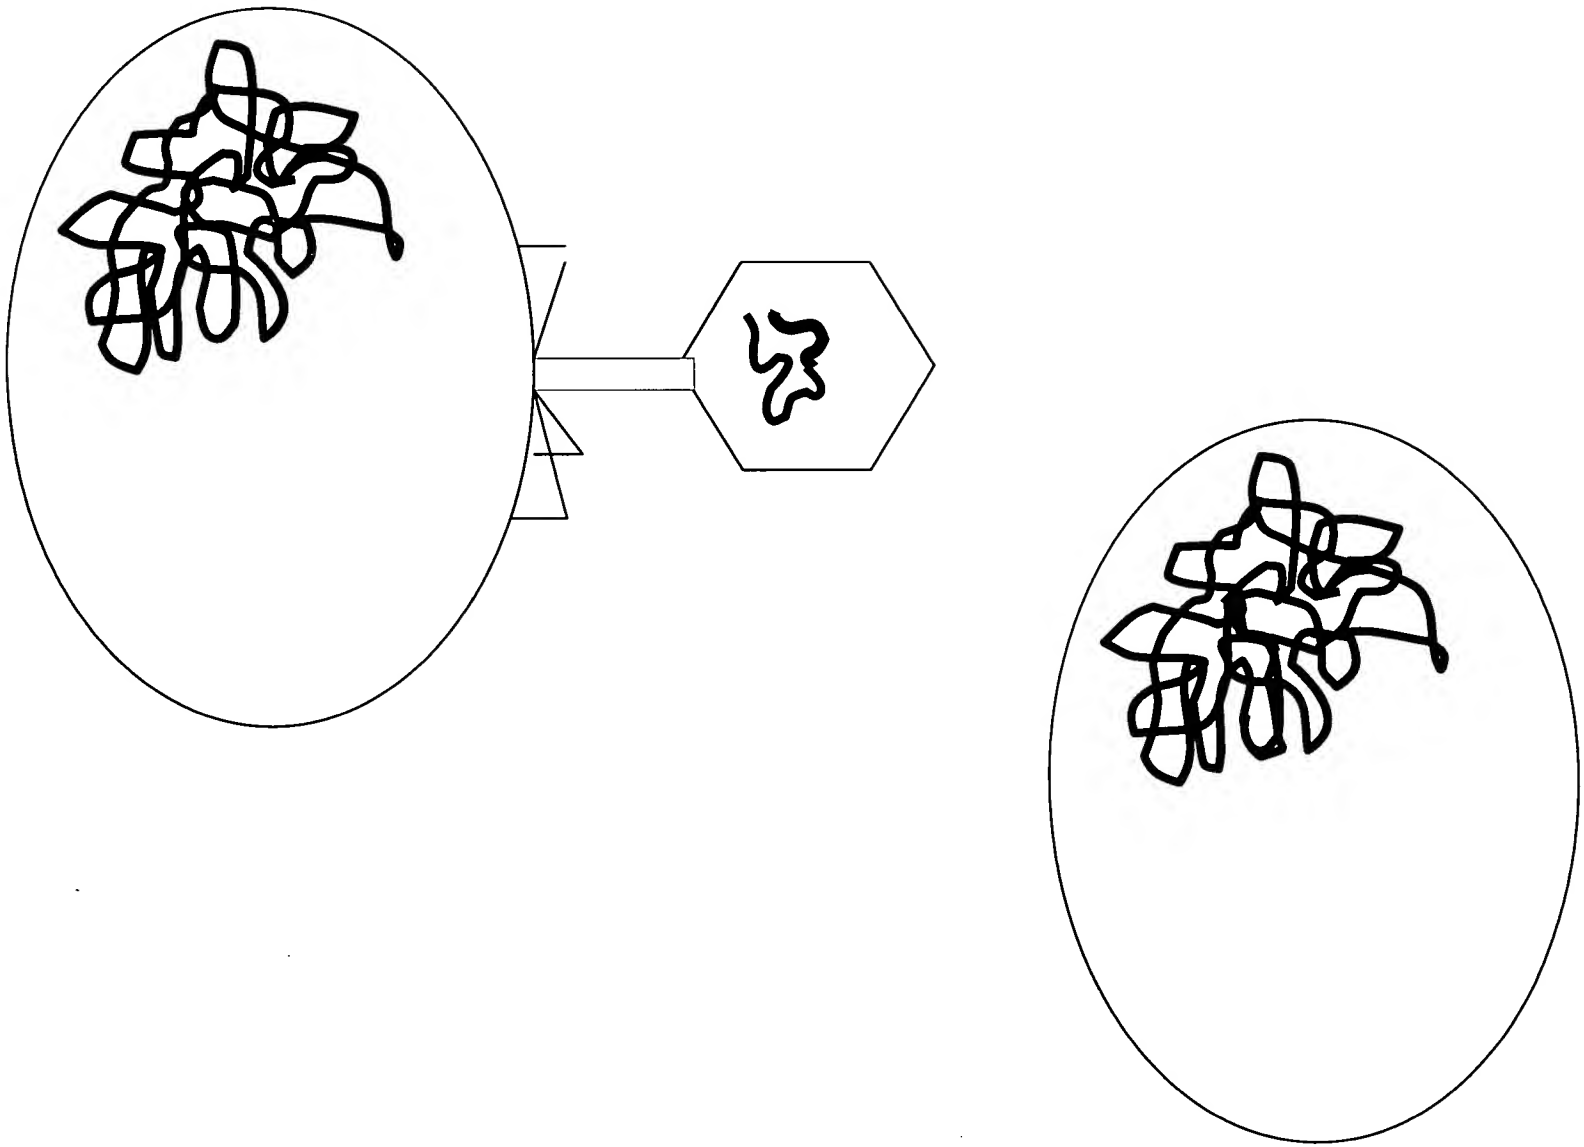
TRANSDUCTION, STEP 2



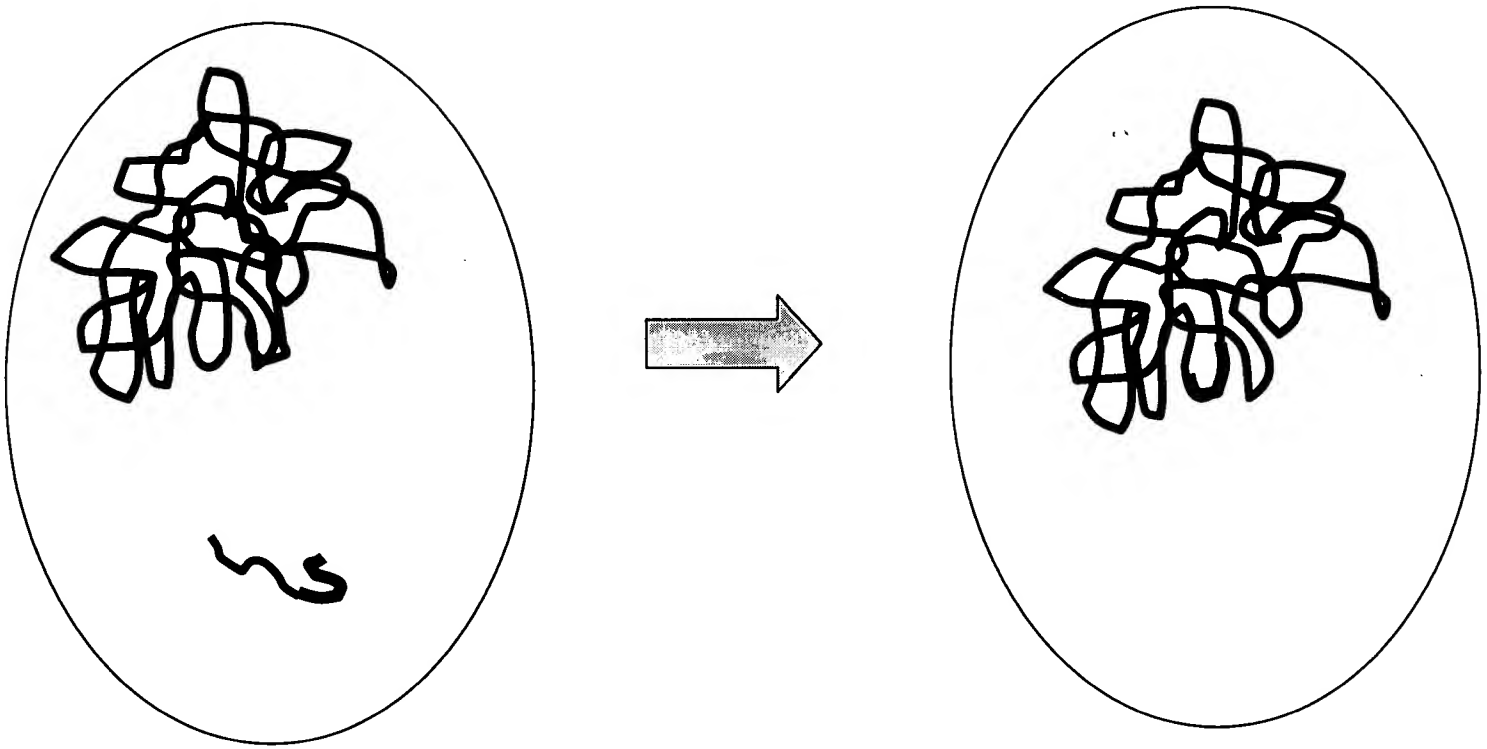
TRANSDUCTION, STEP 3



TRANSDUCTION, STEP 4

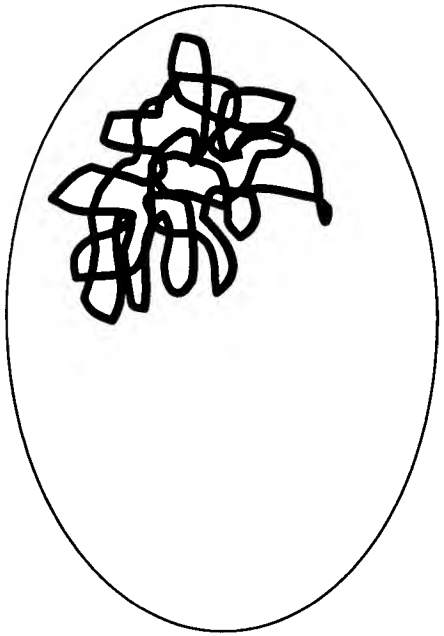


TRANSDUCTION, STEP 5

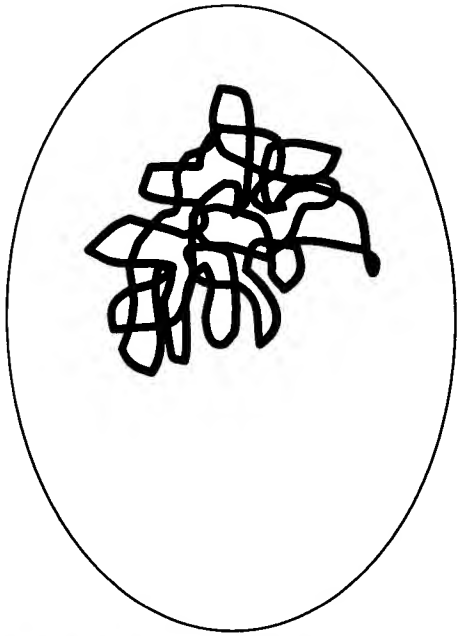


New recombinant cell

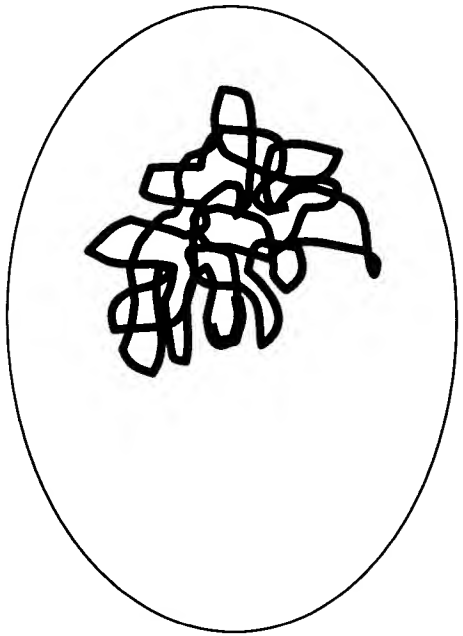
TRANSDUCTION COMPLETE



Starting cell (donor)



Another cell (recipient)



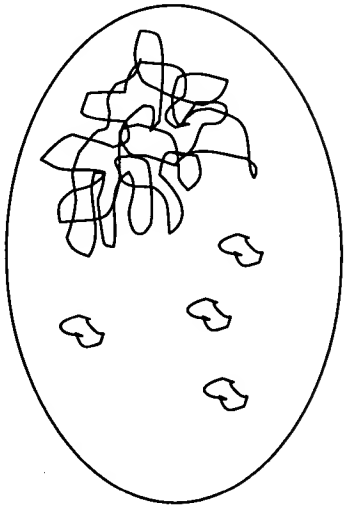
New recombinant cell

3. CONJUGATION

Conjugation occurs when related cells SHARE copies of special plasmids (F-plasmids or R-plasmids)

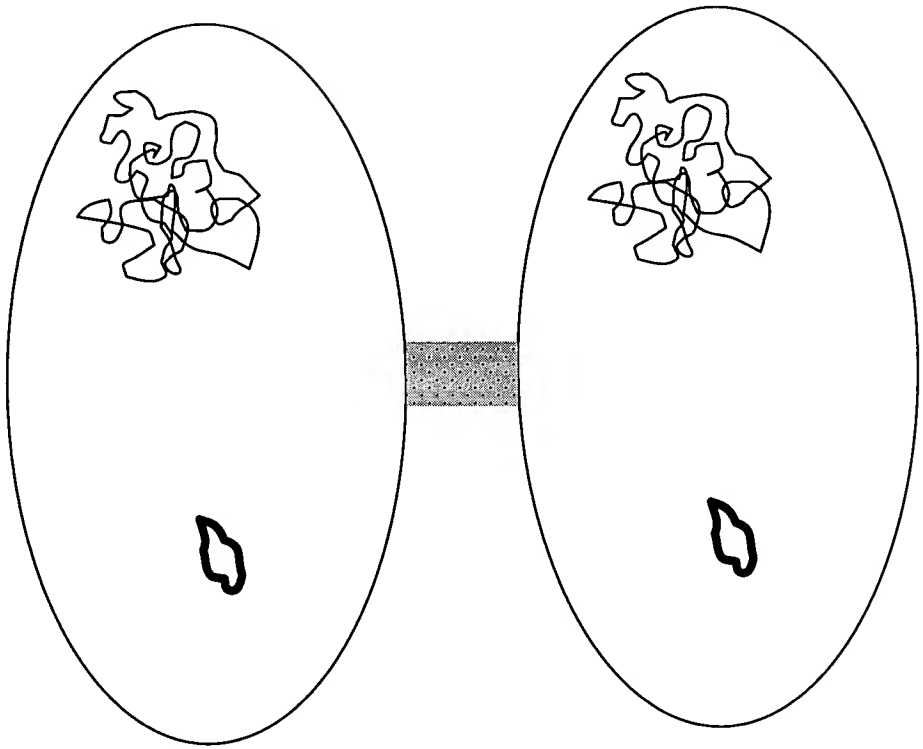
CONJUGATION

First, what is a plasmid????



- Extra-chromosomal DNA
- Gets copied independently of chromosome
- May or may not get carried into daughter cell
- Cell copies plasmid when gene products are needed

- Genes typically present may encode antibiotic or metal resistance proteins
- Closely related cells can SHARE plasmid copies



Donor cell (F+) passes a COPY of F into recipient cell (F-)

Recipient cell becomes F+

CONJUGATION

Requires a conjugative plasmid!

- The plasmid has special genes on it that facilitate conjugation

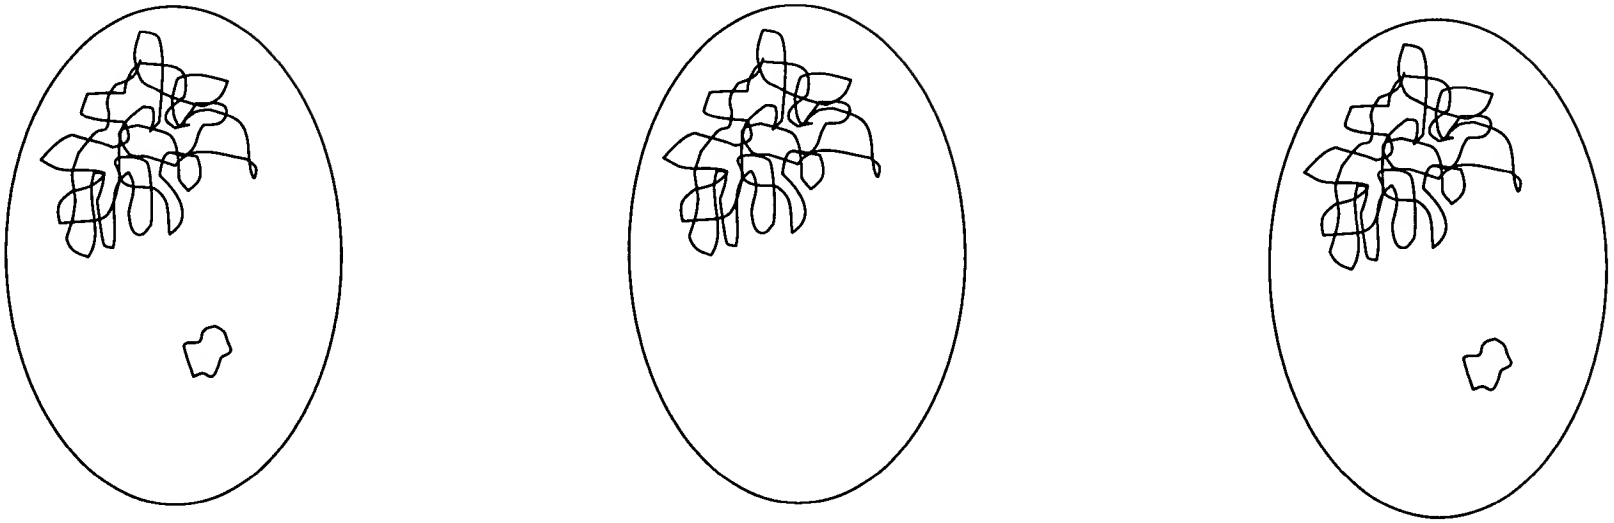
The plasmid genes are not necessary for the cell's growth and reproduction, but they add special abilities

- requires direct cell contact, sex pili involved

Special plasmid is called the F plasmid in E. coli

Cells with this plasmid are called F+ (without, F-)

When an F+ cell shares its plasmid with another cell - the new cell now has a plasmid it never had before. But it is not a recombinant. (Why?)



DONOR RECIPIENT 'NEW CELL'

A NEW RECOMBINANT CELL CAN OCCUR BY THE FOLLOWING MECHANISM:

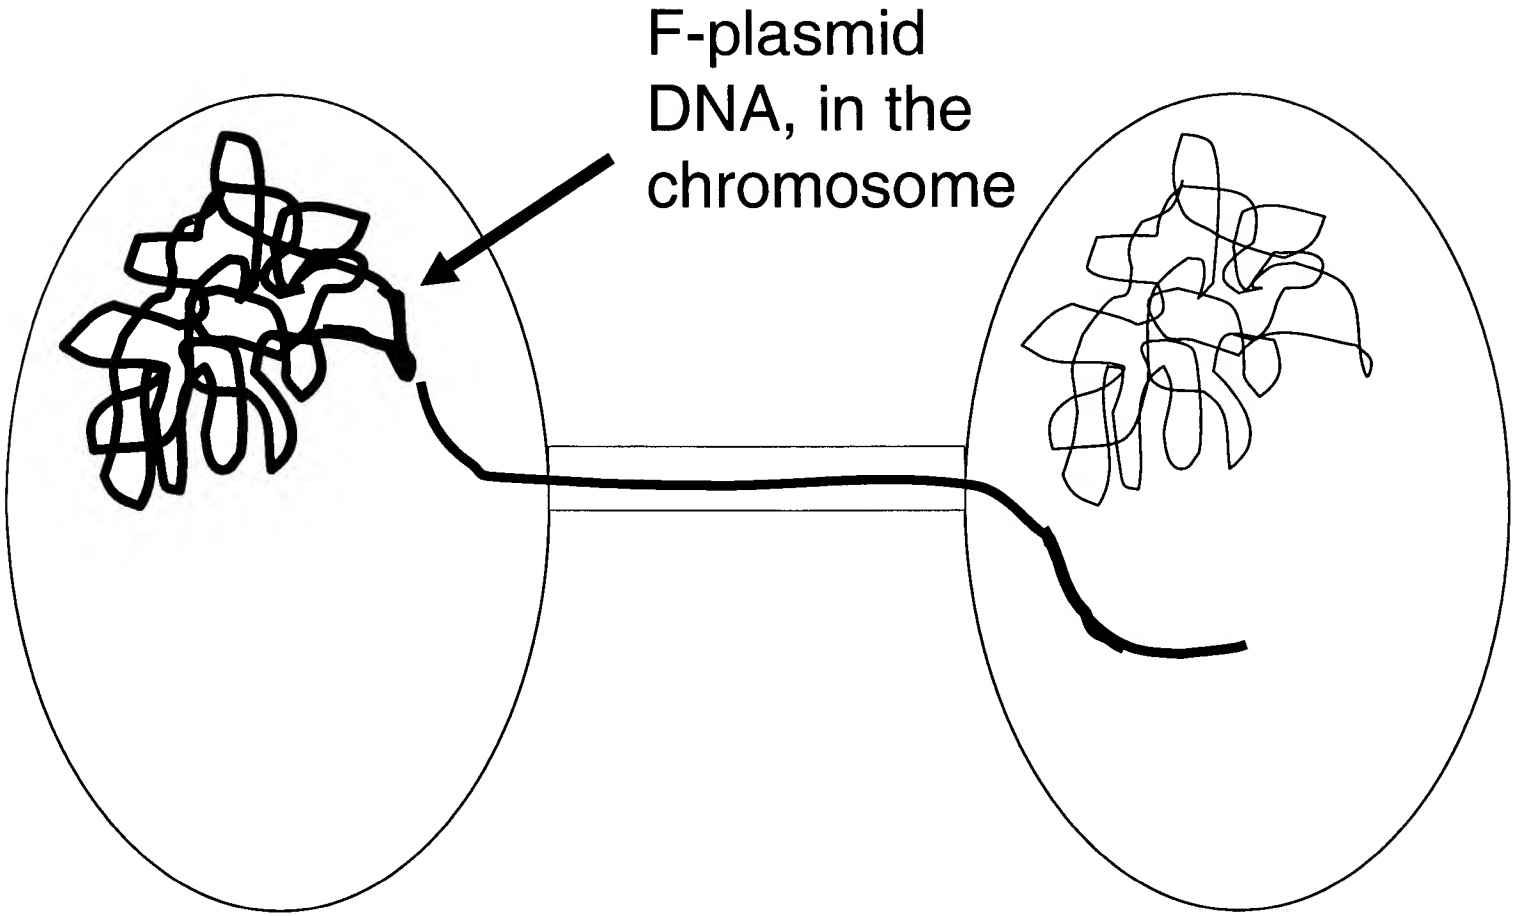
F factor genes can become integrated into the bacterial chromosome.

If they do - we say the cell is Hfr (High frequency of recombination).

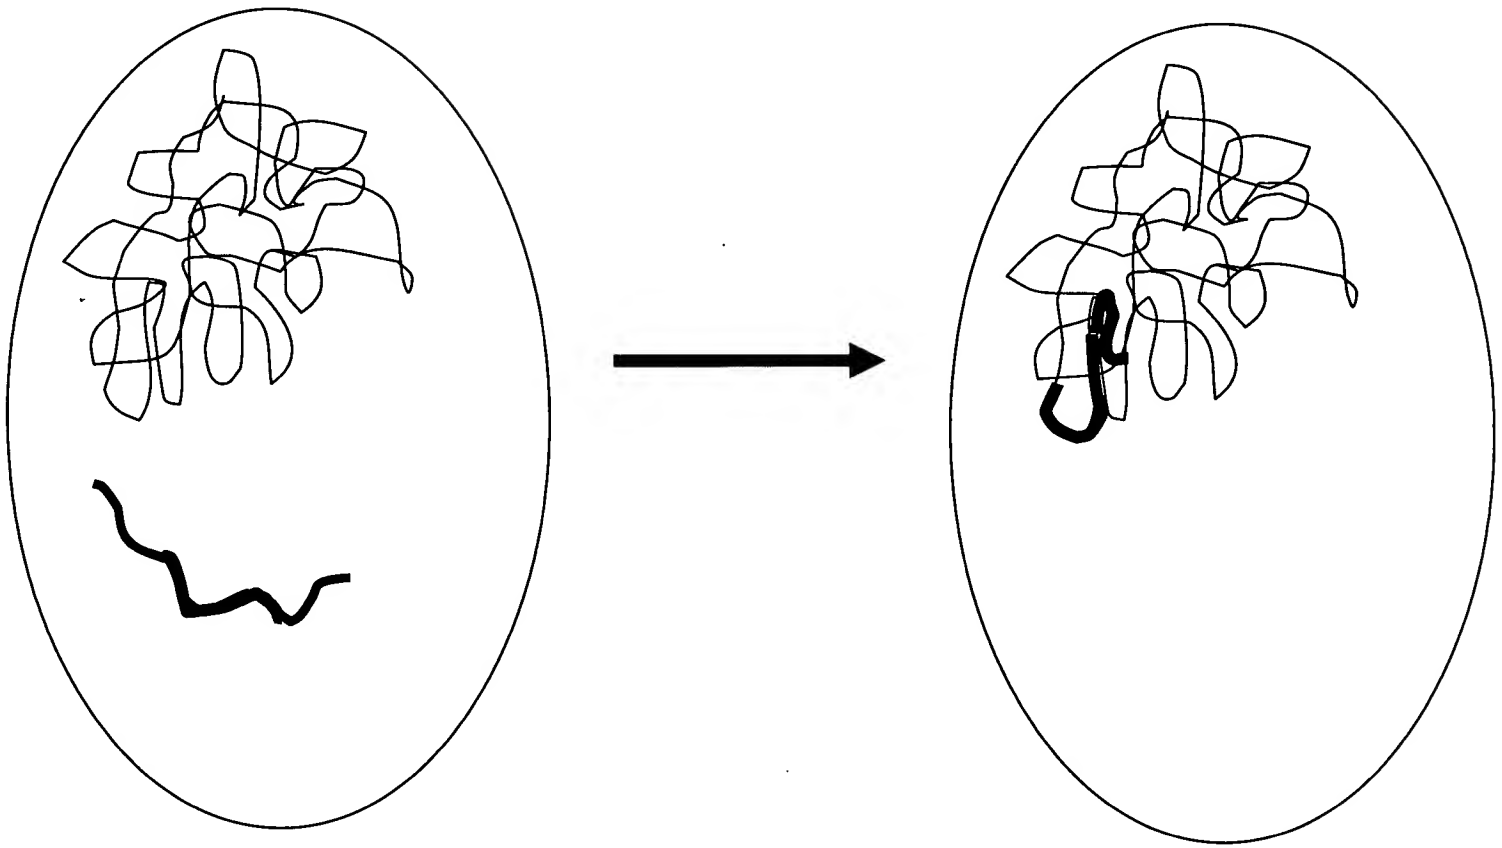
When an Hfr cell mates with an F- cell, conjugation begins just as we have described

But when the DNA is copied and sent into recipient cell, some of the rest of the chromosome may go too!

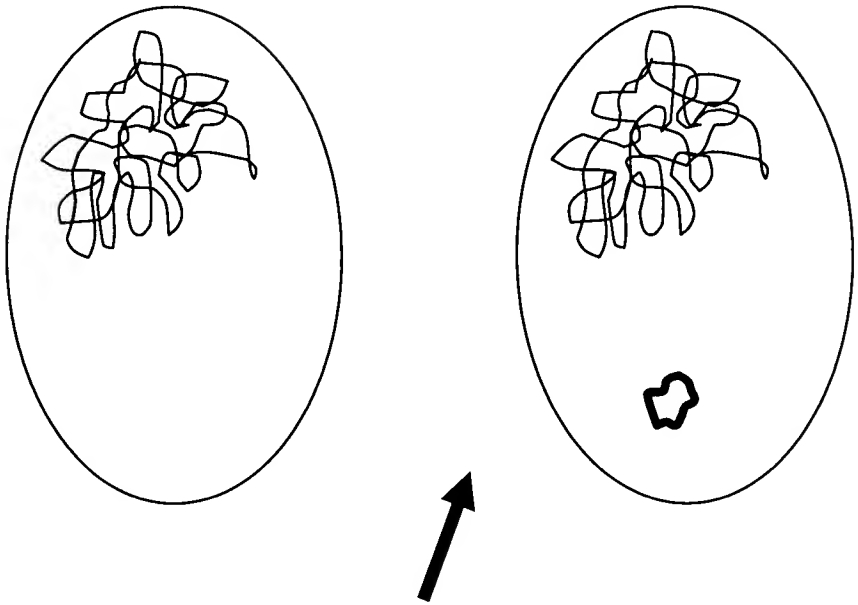
Then, recombination can occur, and the recipient cell has a new combination of genes in its chromosome.



Hfr cell

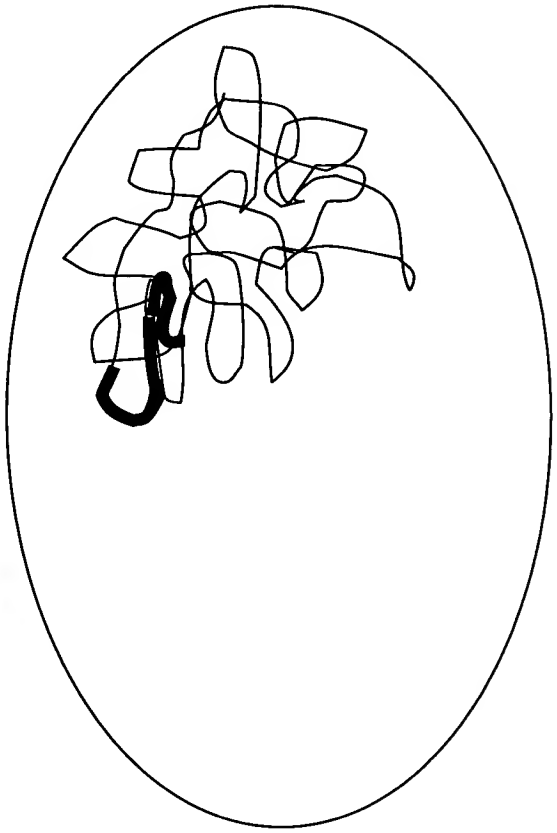


NEW RECOMBINANT CELL



Whereas this cell is not?

Why is this cell a recombinant -



REVIEW:

Bacterial cells CAN achieve variation through mutation

Bacterial cells also achieve new gene combinations through 3 unique processes

Transformation occurs when DNA pieces are taken up from the environment

•Conjugation occurs when cells share plasmids

Transduction occurs when new BACTERIAL genes are integrated into chromosome because of phage infection
